2014 Integrated Energy Policy)
Report Update (2014 IEPR Update))

CALIFORNIA ENERGY COMMISSION
HEARING ROOM A, 1516 NINTH STREET
SACRAMENTO, CALIFORNIA

Reported by:
Peter Petty

APPEARANCES

Commissioners Present (*Via WebEx and telephone)

Janea A. Scott, Lead Commissioner for the 2014 IEPR Update
Lead Commissioner on Transportation

Robert Weisenmiller, Chair

Karen Douglas

CEC Staff Present

Heather Raitt

Moderator

Ann Chan, California Natural Resources Agency

Presenters (* via WebEx)

*John Radke, UC Berkeley
Robert Lempert, RAND Corp.

Also Present:

Public Comment

Martine Schmidt-Poolman, UC Berkeley

1 P R O C E E D I N G S

2 MAY 28, 2014 3:03 p.m.

3 MS. RAITT: Welcome to the Lead
4 Commissioner Workshop on Climate Change Impacts
5 on the Transportation System. This workshop is
6 part of the 2014 IEPR Update.

7 I'm Heather Raitt, lead for the IEPR.
8 And I'll begin by going over a couple of
9 housekeeping items.

10 If there's an emergency and we need to
11 evacuate the building, please follow staff to
12 Roosevelt Park, which is across the street
13 diagonal to the building, and wait there until it
14 is safe to return.

15 Today's workshop is being broadcast
16 through our WebEx conferencing system and parties
17 should be aware that you're being recorded.
18 We'll post an audio recording on the Energy
19 Commission's website in a few days and a written
20 transcript in about three weeks.

21 We have one panel today, moderated by Ann
22 Chan of the California Natural Resources Agency,
23 and we'll discuss the Draft Report Safeguarding
24 California, Reducing Climate Risk.
25 Unfortunately, one of our planned speakers for

1 the panel, Deb Niemeier, is ill and she won't be
2 able to make it and sends her regrets. We plan
3 to be posting her slides tomorrow.

4 We have two presenters today, John Radke
5 from UC Berkeley on WebEx, and Robert Lempert
6 from RAND Corporation. And at the end of the
7 panel, there will be an opportunity for public
8 questions and comments.

9 For those who would like to make
10 comments, we are requesting that you keep your
11 comments limited to three minutes, and we'll take
12 comments first from those in the room, and then
13 from people participating by WebEx. And for
14 WebEx participants, you can use the chat function
15 to tell our WebEx Coordinator that you'd like to
16 ask a question or make a comment during the
17 public comment period and we'll either relay your
18 question or open your line at the appropriate
19 time. For any phone-in participants, we'll open
20 your lines after we've taken comments from in-
21 person participants and WebEx participants.

22 Materials for the meeting are available
23 at the table when you walked in and are also
24 available on our website. We encourage folks to
25 provide written comments as well, and request

1 that those be submitted to us by June 11th, and
2 the Notice for the meeting provides information
3 about the process for submitting comments.

4 With that, I'll turn it over to the
5 Commissioners. Thank you.

6 COMMISSIONER SCOTT: Thank you, Heather.
7 Good afternoon and welcome to everybody. Thank
8 you for joining us for today's workshop on
9 Climate Change Impacts on the Transportation
10 System. I am very much looking forward to
11 hearing the presentations from our presenters
12 today; I'm sorry to hear that Deb Niemeier is
13 sick and hope that she feels better soon.

14 And I'd just like to say welcome to our
15 presenters that we do have here in the room and
16 on the phone. And I will turn to Chair
17 Weisenmiller to see if he has any opening
18 remarks.

19 CHAIRMAN WEISENMILLER: Yeah. I
20 certainly want to thank everyone today for being
21 here. I think we're all becoming more and more
22 familiar that our climate is being disrupted and
23 that comes from the high greenhouse gas
24 emissions. So transportation is really great, we
25 can focus on it, and that about 40 percent of our

1 greenhouse gas emissions in California are from
2 transportation. And at the same time, these
3 changes are affecting our transportation system.
4 And so, as we plan that critical infrastructure,
5 we look at what the implications are of climate
6 change in that planning. So, again, thanks
7 everyone for being here today.

8 COMMISSIONER SCOTT: Great. So I will
9 turn it over to Ann Chan, welcome, from the
10 Natural Resources Agency. And thank you for
11 joining us and I'll let you kick it off.

12 MS. CHAN: Thank you so much. I'm Ann
13 Chan, I'm the Deputy Secretary for Climate Change
14 and Energy at the California Natural Resources
15 Agency.

16 The California Natural Resources Agency
17 actually leads the development of a report called
18 "Safeguarding California: Plan for Reducing
19 Climate Risks in California" and there you see a
20 copy of the document. We put out the first draft
21 back in December of 2010 and it does include a
22 chapter on Transportation and Risks to
23 Transportation from Climate Change, and the lead
24 for that section of the document was actually
25 Caltrans, one of our sister agencies. So that's

1 why I'm here helping to moderate this panel
2 today.

3 I'd like this to be a little bit of an
4 interaction discussion, so what I was hoping to
5 do was just take a few minutes here to give you a
6 little bit of an overview of the materials in the
7 Safeguarding California Plan on Transportation,
8 and then we'll hear from our panelists and then
9 I'd like to reserve a little bit of time before
10 we open up the official Q&A to do a little bit of
11 interactive back and forth with our two
12 panelists, and have some inter-panel discussion
13 if that makes some sense.

14 So as folks may know, there are a myriad
15 of climate risks that California is facing and we
16 know this in part because California has invested
17 in regionally relevant climate science in
18 California through three prior California Climate
19 Change Assessments. We are currently thinking
20 about a fourth Climate Change Assessment, the
21 Governor has \$5 million allocated in his Proposed
22 Budget for a fourth California Climate Change
23 Assessment and the Legislature is still
24 discussing that funding as we speak now in
25 conference this week.

1 Some of the risks we know we face are
2 things like extreme storm events, sea level rise,
3 heat and flooding, and all those things can have
4 impacts on the transportation system and also on
5 the supporting systems, namely the energy and
6 fuel systems that support the transportation
7 systems. So sometimes people forget about how
8 those different systems are interrelated and it
9 makes a lot of sense to be having this discussion
10 here at the Energy Commission.

11 Obviously, the transportation system is
12 really multi-modal. We not only have highways
13 and roads, but we also have rail transit, ports
14 and airports, and California is rich in all those
15 different types of modes. I think one of the
16 challenges with having that kind of a multi-modal
17 system is that not all of those assets are under
18 State jurisdiction, so when we're thinking about
19 State policy efforts to prepare for climate
20 impacts to the transportation system, we really
21 need to figure out how to enhance our
22 coordination between federal, state, local and
23 private entities, as well, because there are many
24 transportation assets under private management,
25 as well.

1 So the Safeguarding California Plan, if
2 you're interested in this topic, really goes into
3 some depth about expected impacts on the
4 transportation system, what we've done to date,
5 and our recommendations for what to do to help
6 reduce those risks. We had an extensive public
7 comment period and we are in the process of
8 finalizing the document and expect it to be out
9 this summer.

10 The stakes are very high obviously when
11 we're talking about climate impacts to the
12 transportation system. Transportation system not
13 only supports our economy, but also personal
14 mobility and emergency services. I think Super
15 Storm Sandy really brought this into focus for a
16 lot of people and eliminated some of these issues
17 in a way that people hadn't thought about before,
18 that it's not just you worry about roads, you
19 also worry about your transit systems.

20 It's not enough just to get fuel to your
21 car, you need to have energy to make sure that
22 you can run the pumps to get the fuel into your
23 car. So it's very timely, an interesting topic,
24 and really looking forward to hearing from our
25 panelists.

1 I think on the agenda our first speaker
2 is John Radke. He's an Associate Professor at
3 U.C. Berkeley and he's joining us by WebEx, I
4 believe. And his research focuses on analytical
5 methods imbedded in GIS or Geographic Information
6 Science. And his interests include the
7 development of metrics that assist scientists and
8 professionals in recognizing spatial structures
9 and changes in complex landscapes. These metrics
10 really help us to advance our ability to classify
11 and make sense of data generated by sophisticated
12 sensors that record a map's spatial distribution
13 of phenomena beyond human comprehension.

14 So I know this is an area of great
15 interest also to the Federal Government. We've
16 been spending a lot of time as the State of
17 California talking with our Federal counterparts
18 about how to take climate data and make it
19 accessible through tools, mapping and
20 visualization for folks so that they can really
21 start using it to help with planning efforts to
22 reduce climate risks.

23 And so with that introduction, I think
24 I'm going to turn it over to John.

25 PROFESSOR RADKE: Now I need to -- can

1 everyone see my slides?

2 COMMISSIONER SCOTT: We can hear you. I
3 think they're queuing up your slides right now.

4 PROFESSOR RADKE: Well, I'd like to show
5 them from my desktop because I have -

6 COMMISSIONER SCOTT: Yeah, go ahead and
7 share your desktop.

8 PROFESSOR RADKE: It should be happening,
9 right? Can you see it?

10 COMMISSIONER SCOTT: Yes.

11 PROFESSOR RADKE: Okay, well, so
12 everything you said was really good because it's
13 the kind of area that we've been working on and
14 we have quite a lot of concerns here. My co-PI
15 is Greg Biging and he's from the Environmental
16 Science Policy and Management Group on the
17 campus, and then Howard Foster, Emery Roe,
18 Martine Schmidt-Poolman are all experts in the
19 Center for Catastrophic Management. And then a
20 number of graduate students in various
21 departments, Landscape Architecture,
22 Environmental Planning, and Geography.

23 And I wanted to mention to everyone, in
24 the wide background that we cover, because we
25 look at lots of complex problems and especially

1 in the Center for Catastrophic Risk Management,
2 which was formed here after Hurricane Katrina, so
3 certainly have been on top of all of the
4 disasters that have come along, and certainly
5 climate change is exacerbating many of those.

6 Today I'm going to talk about two
7 projects that we're doing and I've sort of melded
8 the two together, and I also talk about some of
9 the modeling that we're doing because the
10 modeling has been evolving. And it's been
11 evolving partly out of an interest that the
12 California Energy Commission has, a suggestion to
13 make it more dynamic, but also out of interest by
14 a lot of the people that control and own
15 infrastructure and have expressed concerns, so
16 we've met with a lot of them as well.

17 Sea level rise, and hopefully I'm
18 preaching to the converted here, this is coming
19 from Dan Cayan, says that by 2100 it will be a
20 1.41 meters rise in sea level in the Bay Area,
21 and he said that earlier this year. People are
22 generally worried about areas that fall within
23 the sea level rise borders and that's important.
24 I know that the Governor had mentioned earlier
25 airports and, of course, we did the study looking

1 at San Francisco Airport and the Oakland Airport,
2 and they are stressed by the year 2100. And so
3 something has to be done to protect those. And
4 you'll see by the end of my presentation here
5 that there are some other areas of transportation
6 infrastructure that not only are stressed, but
7 actually get inundated and are probably not
8 savable without some serious rethinking, possibly
9 rethinking the design and location, or rethinking
10 how we're going to defend them.

11 All right, so here is a picture of a
12 storm. This is not a 100-year storm event, it's
13 far less than that. It's out on Sherman Island,
14 it's out on the levee, and the picture on the
15 right-hand side is Hamilton Field and you'll see
16 the purple lines happen to be the gas pipelines
17 running through the area, and the yellow lines
18 happen to be the highway infrastructure. And you
19 can see the roads, as well, in that picture and
20 you'll see later on, this next picture on the
21 left is a truck driving along the levee, you can
22 just barely see it, it's being inundated by that
23 less than 100-year storm event, which means the
24 infrastructure and the road transportation
25 systems being impacted, and you'll see later that

1 the levees can get impacted, and what the
2 repercussions of that on the transportation
3 system are.

4 On the right-hand side, what you're
5 seeing is Hamilton Field inundated and you're
6 seeing that both roads, houses, and the gas
7 pipeline infrastructure is impacted.

8 So but not just inside where the sea
9 level will rise, but we have to look outside that
10 area because it will also be affected, and that's
11 what I've tried to point out on several talks
12 that I've given, that those that live outside the
13 area may feel they're not going to be impacted,
14 but in fact they are.

15 There is this domino effect of things
16 that are interconnected, interdependent
17 infrastructure. And this is a diagram by Don
18 Boland, the Executive Director of California
19 Utilities Emergency Association (CUEA). And we
20 see this, all of these infrastructure
21 transportation up in the right-hand side, but
22 they're all affected -- natural gas, telecom,
23 electrical power. And when one is stressed, or
24 one starts to degrade, or is broken, the other
25 ones are affected by it.

1 And the transportation study we completed
2 for the Bay Area, and I'll be talking about that,
3 and I'll also be talking about the present study
4 that we're doing on the gas pipeline
5 vulnerability. Both projects look at inundation.
6 And it's been sort of an ongoing effort on our
7 part to try to get this right and becoming as
8 accurate as we can because, of course, we've been
9 flooding the Bay Area for a long time using
10 different models. And in our transportation
11 model, we looked at sea level rise, and we looked
12 at increments of no sea level rise to .5 meter,
13 1.0 and 1.4. Notice earlier, I said Dan had
14 suggested that by the end of the century, it will
15 be at 1.41, and that's an adjusted mark, and that
16 may be adjusted even further given what we learn
17 every day. But for this transportation study, it
18 was 1.4, and so we just took that one as a
19 benchmark.

20 We add the 100-year extreme storm event,
21 and this is an event that comes along once every
22 100 years, but in some of Cayan's recent and
23 Bromirski's recent research, they've shown that
24 this event will start to repeat itself until by
25 the year 2100, it comes back every year so it's

1 no longer a 100-year storm event.

2 Then we use a pathway model rather than a
3 bathtub model, and the pathway model we used
4 because it shows us that some people predicted
5 with their models using a bathtub that this would
6 be the inundation in the North Bay and, of
7 course, we using a pathway, we realized that
8 levees are quite effective and keep the water
9 out. And so we used this pathway model in our
10 transportation study and we moved on to different
11 models that we're using today, as well.

12 Both projects look at inundation and the
13 Gas Pipeline Vulnerability Study, it looks at the
14 same rise in sea level; we add to that a near
15 100-year storm event, and I'll explain why we're
16 using a near 100-year and not a predicted 100-
17 year storm event, but in this model, in this more
18 recent research we're using a dynamic process and
19 it incorporates Diurnal tides and Peak water
20 levels during storm events, and so we actually
21 rather than running the model once and looking at
22 sea level rise and predicted height of wave, we
23 look at the pounding of the waves against the
24 shore and we look at how much they go inland and
25 how much they retreat. And it turns out, through

1 our discussions with some operators of gas
2 pipelines that this is quite a concern of theirs
3 because some of the infrastructure was not
4 originally built to deal with their pipelines
5 being under water for certain extended lengths of
6 time. So it turns out that water movement and
7 water depth are quite important. When we first
8 started the project, we weren't concerned about
9 that, we were more concerned about swelled
10 failure, and I think that was brought on by some
11 accidents that had occurred earlier and by some
12 of the information that had come out of Katrina
13 and some of the decisions they made in Katrina to
14 change infrastructure. But we've now been sort
15 of enlightened and we realize that the amount of
16 water and how it's sloshing throughout and on top
17 of some of these infrastructures is quite
18 important.

19 Of course, looking at the Improvement of
20 Inundation model, we're starting to model the
21 movement through the different gauging stations
22 and some of them we predict from using an
23 inundation model, and some of them are real data.
24 So we've been able to calibrate our model.

25 So let me just show this movie and this

1 is near Mission Bay and it's over a 24-hour
2 period, and this is the sea level has risen 1.4
3 meters and we're at a near 100-year storm event,
4 and I'll explain a little bit about that later.
5 But as you see here, the water came in and
6 inundated the land, and then it started to
7 recede. But hopefully you can see my cursor.
8 Can you see my cursor, the little hand?

9 MS. CHAN: Yes.

10 PROFESSOR RADKE: And this is the end of
11 the high speed rail line, I believe, and of
12 course over here is U.C. San Francisco, and we
13 see remnants of water still left, so this area
14 has been flooded. And during the movie, the
15 water went inland and then came out again, so
16 things further inland were impacted.

17 So this new way of modeling is telling us
18 how it's going to hit the landscape and how it's
19 going to move on land, but we're seeing
20 transportation infrastructure and pretty critical
21 transportation infrastructure, and then just
22 regular infrastructure being impacted by it.

23 All right, so components to estimate our
24 potential inundation areas, and that actually
25 takes an awful lot to do this because we're not

1 doing this at low resolution, we're doing this
2 for the entire Bay Area, the Delta, and we're
3 heading down the coast. And for the Bay Area and
4 Delta, we've been modeling it at one meter
5 resolution, but we've taken data from Lidar and
6 some of the point clusters are every few inches,
7 and you'll see some examples of this. It's kind
8 of hard to see, to show results on a screen
9 because we do it at such a high resolution, and
10 it's pretty hard to fit it onto a screen.

11 We model the sea level rise through four
12 iterations, and we do this because the
13 circulation models show us that 1.4 meters is
14 likely going to be what's happening at the end of
15 the century. We entered the 100-year extreme
16 storm event and for the transportation model we
17 did this one in the upper right-hand corner 2.6
18 as the hundred-year storm event, and that was the
19 theoretical one, and we actually modeled that for
20 the transportation. But for the gas project that
21 we're on now, we're modeling it at something that
22 is close to a 100-year storm event, and I'll
23 explain the reason why we chose this 1998 storm
24 event. We need to calibrate our models. And if
25 we look over the 100-year extreme storm events,

1 we find that there are some peaks, and we see one
2 in '82-'83, and we see a peak in '97-'98, but
3 those were El Niño years. And we chose the 1998
4 for the simple reason we needed to calibrate our
5 model, and in calibrating, of course, we're
6 looking for the highest peak events, and it
7 happened on February 6, 1998, but there was
8 something else that was important. Here, the
9 reporting stations -- and these are just the DWR
10 reporting stations, we have many others that
11 we're using -- but these were kind of critical
12 because we're modeling out in the Delta and we
13 need to calibrate our model based upon what the
14 gauging stations were showing, and it turns out
15 that in 1998, there were 21 stations reporting.
16 And in the other events, some of the stations
17 moved on and off line during the event, so we
18 thought the more data the better and it's a near
19 100-year storm event.

20 We needed land surface models and we
21 needed bathymetry, we needed digital elevation
22 models, and we needed digital surface models, and
23 that's just an example on the left of the
24 transportation study that was the coverage flown
25 by the U.S.G.S. and I believe also NOAA. And

1 this is the 100-year storm events, and this is a
2 three-dimensional model, and like I said it's
3 hard to show this because I'm zoomed out and what
4 I've done is I've draped over a surface of
5 pixels, I drape the elevation so you can see the
6 Transamerica Building there on the left, and this
7 is down by the waterfront. And this is a 100-
8 year, or near 100-year storm event, very very
9 close. And of course this is what it looks like,
10 I've draped kind of an image to show you and
11 that's the 100-year storm event, you see some
12 inundation taking place just down by the Ferry
13 Building, and the streets are getting wet and the
14 waves are breaking over, but things are pretty
15 reasonable. But then when we add 1.4 meters, we
16 see the inundation starting to go further inland
17 and we see places that are just completely
18 overwhelmed by the water. So we're modeling this
19 at a very very high resolution, we're modeling
20 the water breaking over levees and breaking over
21 barriers, trying to understand what its effect
22 and what its impact is behind these barriers.
23 And for the current studies that we're on now,
24 we're quite interested in whether or not this
25 water, how much it impacts the land, and whether

1 or not there's infrastructure underneath, or
2 there that's going to be damaged. In the case of
3 gas, we're really trying to work out the
4 infrastructure.

5 In the transportation infrastructure
6 study, we looked at a couple of things. We're
7 interested in the vulnerability of the road
8 network. And, yes, we looked at the airports, we
9 looked at trains, but we also looked at the road
10 and we reeled the model that's out because we
11 were interested in showing not just sea level
12 rise and the impact on the land, but also what
13 impact it would have in the region, as well, so
14 some people would feel, well, I don't live near
15 the ocean, so I should be safe, but of course
16 then they realize that they can't actually go
17 anywhere because the infrastructure gets broken.

18 And we don't get -- first responder
19 accessibility is kind of important and certainly
20 during 100-year storm events, or any storm event,
21 you want to make sure that first responders can
22 get there. And then we also looked at node-to-
23 node accessibility of the major corridors because
24 if they start to break down, then that's the
25 backbone of your infrastructure and then you need

1 to be concerned there major low corridors are
2 gone. And then we also looked at the Hinterland
3 accessibility to those major traffic corridors
4 because, if you look at these breaking down, then
5 you have a sense of how damaged the system is.

6 And these are just a couple of examples
7 from that study where you see up in Richmond to
8 the north, and down in the South Bay near
9 Milpitas and Sunnyvale, the gray areas are the
10 areas that are inundated with the 100-year storm
11 event, but with no sea level rise. And here we
12 have sea level rising 1.4 meters and we see up in
13 Richmond, basically that area where the bridge
14 starts is now an island, broken away from the
15 rest of Richmond. And we see that even highways
16 in the South Bay, major highways, are starting to
17 be cut off because they used to be on the land.
18 And those red dots are the first responders, and
19 those are the fire stations. And we see in the
20 South Bay we've actually lost two fire stations
21 that are now completely surrounded by water,
22 completely inundated.

23 The point of this was to try to
24 understand if the first responder system would be
25 broken. It turns out that it's not so serious

1 because, as you lose land and you lose houses and
2 you lose infrastructure, you also lose first
3 responders and yet you have enough left over.
4 And that just means we did a good job of placing
5 our fire stations strategically so they can keep
6 serving. But it doesn't help in that they've
7 also been impacted.

8 But if we look at the road network a
9 little further and we look at it regionally, we
10 start to see other things that are not so easily
11 digestible, and one is the domino effect of the
12 interconnected, interdependent infrastructure.
13 We have the node-to-node accessibility and, when
14 we model that out with the 100-year storm event
15 and a zero meter rise, this is just a schematic
16 showing how much extra time it takes to move
17 through the system, and it's not so bad. It just
18 shows one connection between nodes 17 and 18 in
19 the upper left-hand side, that suddenly has
20 difficulty and it starts going four to five times
21 increase in travel time, and that's in the North
22 Bay, and that's the highway going across from
23 Marin to Sonoma, and then a 100-year storm event,
24 it gets impacted. But if we raise the 1.4 meters
25 and we start to do the 100-year storm event, we

1 start to see the system collapse and we are
2 starting to lose major nodes in the system, and
3 suddenly what used to take maybe 50 minutes is
4 now taking six or seven hours, and it's just
5 impossible to move around from one major node to
6 the other. And this is just an example of the
7 cross bay infrastructure that starts to break
8 down.

9 Looking at the Hinterland, that's how can
10 I get to those major nodes so I can move around,
11 we see those also start to break down, and
12 especially up in Marin County, we can't even move
13 from A to B, we're going to have to redesign that
14 infrastructure and possibly rethink how we're
15 going to move vehicles on roadways around the Bay
16 Area in the future.

17 Well, let's go up to the Delta because
18 the Delta is a really interesting landscape, very
19 very different than the Bay Area, and it's made
20 up of levees, islands that have earthen levees
21 around them, we have 11 miles of levees, and I
22 could spend the entire day just talking about the
23 Delta. But in this case, we wanted to look at
24 first responders again, but we wanted to look at
25 what happens in the Delta if, in fact, we lose

1 entire islands because in the Delta it's not just
2 about a levee getting inundated, once it's
3 inundating the breaks and the island fills up, it
4 could take three, four, five, six months to pump
5 the water out of the levee to repair it -- pump
6 the water out of the island and repair the levee,
7 and that's because it gets too dangerous to try
8 to patch a levee during a breach. And the
9 technology today doesn't do a great job. And so
10 talking to the experts, it's safer to let the
11 islands fill up and then pump it out later.

12 So on the left-hand side are the number
13 of times, as the patches get deeper red, the
14 number of times that the levees have broken and
15 the islands have been inundated. And I had a
16 bunch of pictures showing lots of water and lots
17 of houses in water up there, but I'm just going
18 to show you maps today.

19 On the right-hand side is the probability
20 of failure and this probability of failure came
21 out of a number of studies, one that I worked on
22 with Bob Bea here at Berkeley, but also a lot of
23 reports that have come out of the Delta. So we
24 know that a lot of these islands are at risk.
25 Well, what happens? And here is Sherman Island

1 and here is just looking at a simulation, we're
2 using a simulation model that takes a look at the
3 tides and the wave structure and looks at the
4 surface, both at digital elevation and surface
5 objects such as buildings, and it models the
6 inundation throughout the island.

7 And so let me just show you the movie,
8 here is the infrastructure and here is the island
9 flooding, and this is what would happen if sea
10 level rose and then the levee breached naturally
11 where the levees were lowest, and you can see it
12 goes in and it basically inundates all the
13 infrastructure, both roads and gas infrastructure
14 at this point.

15 Now, let's look at the first responders.
16 So, again, looking at the domino effect, and the
17 area on the left is where we had Lidar data, high
18 resolution data, for the entire delta. And the
19 area on the right is the islands that we've
20 flooded, and we've flooded them one at a time, so
21 we did a gaining idea where you flood, and then
22 you recalculate how inaccessible or how
23 accessible first responders are to rescuing
24 people, and you just keep iterating this over and
25 over and over again. And you do this to try to

1 find out, well, who in no matter what scenario
2 who is really in the worst case? And here are
3 the first responders up from the island and, of
4 course, on the right here is the result. Now,
5 again, I could spend an hour talking about this
6 study, but in the end we have these three circles
7 and within these three circles, the people that
8 live here are the people that are living in the
9 worst scenario in that every time islands are
10 flooded, no matter what the scenario is, over the
11 entire reach of it the probability of these
12 people becoming inaccessible to first responders
13 goes up. So that's where you don't want to live
14 on the Delta, or you want to actually start to
15 put first responders in the middle of these areas
16 to possibly help the people.

17 And so this is again trying to show that
18 the transportation network might break in one
19 place, it might be fine in another, but over a
20 whole series of scenarios these are the places
21 that aren't accessible.

22 Gas pipeline vulnerability study. So
23 this is Hamilton Field, I told you about the
24 purple lines here are gas pipelines, and this is
25 the end of our study, this is 1.4 meter rise in

1 elevation, and this is the land that is being
2 inundated by the 100-year storm event. What's
3 critical here is those purple lines are the key
4 pipelines that connect north and south. And you
5 can see that one is completely inundated and the
6 other one over there by Highway 101 is also very
7 close to being inundated. So already what our
8 study is showing is that we have a critical piece
9 of infrastructure here, and it's the north/south
10 infrastructure and it's going to be stressed for
11 sure.

12 Now we use a model called 3Di, the model
13 that the Dutch have been developing, they've
14 developed several innovation models mainly
15 because I think more out of necessity because
16 they spend most of their time living below sea
17 level. And we looked at three of them, and this
18 is the third one, and this is the one that can
19 actually model at very high resolution, very
20 large extents, and does a very good job and this
21 is the one we've been using.

22 Now, this is what cross sections look
23 like. Here we have sort of a typical area where
24 we have a bit of a levee here, it gets
25 overtopped, the water comes in behind, but then

1 we start going up the side of the higher
2 elevation and you can see these little peaks here
3 might simply be roads or they might simply be
4 certain levees or barriers, but once we start
5 going up it's pretty safe likely to be building
6 infrastructure up in this area. But then we have
7 other parts of the Bay where we have some levees,
8 but then when they get broken, the water gets
9 behind, it keeps breaking, and it goes much
10 further. And here we have a rail line, another
11 rail line and a highway, and we see that even at
12 1.4 they get overtopped and water gets in behind
13 them, and this area is up north near Suisun Bay.

14 So those are the two different kinds of
15 edges that we've been modeling. And preliminary
16 results from the Hamilton region, and I'll just
17 run this movie as well, let me go back one here,
18 there we go, and of course the U.S. Corps has
19 already broken a levee and they're starting to
20 make this a wetland, which is probably a good
21 thing because a good wetland will act as a good
22 protective device. But here we are inundating
23 and actually this is the area where we have our
24 gas pipelines, and there they are, you've seen
25 that just a little earlier in this slide.

1 So some of our preliminary findings, we
2 again used a very preliminary set of runs over a
3 model, not the highest resolution, and we found
4 that we have a lot of pipe segments, about 498
5 gas pipeline segments, that get inundated, and
6 that's 171 miles. But notice they are bits and
7 pieces of a pipeline and so we're still in the
8 middle of this study, so everything is
9 preliminary right now.

10 We're talking with PG&E under a
11 Nondisclosure Agreement to understand what the
12 cost of repairing or possibly what their strategy
13 might be to rethink and redesign a pipeline. And
14 that's where we are. So, questions?

15 MS. CHAN: We're actually going to hold
16 the questions until after both panelists have
17 spoken, so thanks for that presentation and we
18 are going to move on to our second panelist, who
19 is Robert Lempert, who is a Senior Scientist at
20 the RAND Corporation and Director of the
21 Frederick S. Pardee Center for Longer Range
22 Global Policy and Future Human Condition.

23 DR. LEMPERT: I'm still looking for an
24 acronym.

25 MS. CHAN: That's a mouthful. His

1 research focuses on decision making under
2 conditions of deep uncertainty with an emphasis
3 on climate change, energy and the environment.
4 And I'll pause for an editorial comment there. I
5 know there's been a lot of bandying about in the
6 process of the word "uncertainty" and "climate
7 change", and uncertainty is the reason why we
8 don't take action on things. Obviously, in our
9 everyday lives we deal with a lot of uncertainty
10 and I think another way to think about that is
11 about risks and how we manage risks in our day to
12 day life. I know one of Dr. Lempert's degrees
13 has to do with science policy, so he's not only a
14 physicist, but he also has a policy perspective,
15 as well. And he did his schooling at that other
16 school on the East Coast, but we'll try and
17 ignore that, he studied at Harvard for both his
18 degrees.

19 DR. LEMPERT: No, no, I was at Stanford
20 for undergrad.

21 MS. CHAN: Oh, Stanford, okay, he's cool.

22 DR. LEMPERT: Okay, great. Thank you
23 very much. And actually I think you guys have
24 done a really nice job of putting together the
25 talks because John talked about a series of risks

1 and vulnerabilities, my talk is going to be how
2 to think about -- and some of those may happen in
3 decades, some of those may be happening now in
4 terms of the shift of storm frequencies, and I'm
5 going to talk about how to think about bringing
6 that information into near term decisions, what
7 we do today.

8 And so my talk really has two parts. I'm
9 going to talk about a study where we worked with
10 the Port of Los Angeles, helping them think about
11 how to bring information on potential extreme sea
12 level rise into their infrastructure investment
13 decisions. And I'll say specifically what those
14 are when I get to them in a little bit. And the
15 study is essentially a demonstration of an
16 approach for thinking about how to include
17 information on climate extremes into
18 vulnerability and risk assessments. And I'm
19 going to begin with an overview of the approach,
20 and then apply it to the Port of Los Angeles.

21 So, I mean, this is sort of the overview
22 theme that much of our work tries to get at,
23 which is the point that managing climate risk
24 poses both analytic and organizational
25 challenges. As you all well know, and public

1 paneling is supposed to be objective, it's
2 supposed to be clear rules and procedures
3 accountable to the public; on the other hand, if
4 you look at what climate change has in store for
5 us, there's this fast moving, fast changing,
6 sometimes irreducibly uncertain science,
7 competing interests and values, long time scales,
8 though sometimes what seems long is going to come
9 soon, and vice versa, and then the near certainty
10 of surprise.

11 And in some contexts, it's obvious what
12 you do and you deal with fast changing and
13 surprising worlds, you try to be robust, you try
14 to be flexible, but that's often hard to
15 integrate with our public policy procedures,
16 which are meant to be clear and accountable and
17 understandable to the public.

18 There is a framework for dealing with
19 this, this is called "iterative risk management,"
20 this is a chart from the recent IPCC,
21 Intergovernmental Panel on Climate Change
22 Assessment Report, and basically it suggests
23 going through a process of scoping your decision,
24 doing analysis, implementation and continual
25 updating and revision as we learn. What I want

1 to talk about is how to think about bringing
2 climate information into this process, in a
3 constructive way.

4 And just to remind you that our climate
5 is changing significantly and in hard to predict
6 ways, this is another chart from the recent IPCC
7 Fifth Assessment Report; much of my work is
8 actually in water, water supply, drought and
9 water management, and so this is the
10 precipitation projections that are in the IPCC
11 Report for two different emission scenarios, low
12 and high, and it shows precipitation globally,
13 and the point I want to make here is that the
14 report looks at 30, almost 40 different climate
15 models, and where the difference in whether it
16 gets wetter or drier in a particular place is
17 larger than the mean.

18 So in where there's hatching is we're not
19 even sure yet whether it gets wetter or drier,
20 which is a particularly gnarly issue for water
21 managers. But this is this concept of we know
22 things are changing, but we're not sure how.
23 There's a well-developed body of risk management,
24 but sometimes it is sort of fine-tuned for
25 situations where the uncertainty is relatively

1 limited, and sometimes my colleagues and I stick
2 this name "Agree on Assumptions Approach" where
3 you first lay out what future conditions are
4 going to be and then, using that information, you
5 see what is the best near-term decision, and then
6 you may do some sensitivity analysis. This works
7 great for a number of problems, and I always say
8 you'd never get on an airplane where the people
9 who built it and flew it didn't work really well
10 in this environment and from this sort of method.

11 In the types of problems that we're often
12 dealing with, this process can go awry, that
13 there's a real pressure to underestimate the
14 uncertainties because if you admit how big they
15 are, then it makes it hard to make decisions.
16 The converse, and I'm sure you're much more
17 familiar with this than I am, is that, you know,
18 policy recommendations are often contingent on a
19 projection, and if you don't like the policy you
20 attack the projection because that's often easier
21 to attack than the policy, and so you can get
22 gridlock. And then a little bit more subtly, we
23 often know a lot about a problem which is not
24 very predictive, but can be very good at
25 distinguishing between wise and less wise

1 policies.

2 So a way to deal with this in analytics
3 and in forming these risk management and risk
4 assessment issues is, as opposed to going
5 forward, you can go what we call going backwards,
6 so instead of focusing the analysis on everybody
7 agreeing on the assumptions, and from that moving
8 on to the decision, you allow people to come in
9 with different assumptions, but you work hard to
10 use the analytics to help people agree on what to
11 do, even if they believe different things can
12 happen. So essentially the way you do that is
13 you take a set of proposed strategies, you use
14 your analytics to think where those strategies
15 work well and work poorly, from that information
16 you can think about strategies which may work
17 well across a wide range of different futures.

18 So we have a particular way that we do
19 this which we call "robust decision making" and
20 essentially you go through an iterative loop like
21 this, you structure the decision often working
22 with stakeholders, and I'll get to that at the
23 end, you run your analytics, your models,
24 projections many times. From that, you construct
25 scenarios which tell you the types of futures and

1 which policy may work well, where poorly, we call
2 that "scenarios that eliminate vulnerabilities,"
3 and from that you can look at the tradeoffs and
4 work around this process and come up with robust
5 strategies which work well over a range of
6 plausible futures.

7 So let me take you through this process
8 for the study we did for the Port of Los Angeles,
9 and this was very focused on a particular set of
10 infrastructure, and I'll broaden it at the end,
11 but the particular question we helped them look
12 at is should they or should they not harden their
13 terminals, you know, their big container ship
14 terminals against extreme levels of sea level
15 rise at the next upgrade. And essentially every
16 period of time, it's been every few decade or
17 decade and a half in the recent past, they do a
18 major retrofit of these large terminals, and at
19 that time it's relatively inexpensive to put in
20 hardening against an extra meter of sea level
21 rise; but if you don't do it then, it's really
22 expensive to respond. So should they, given
23 things like the West Antarctic ice sheet that's
24 beginning to crack, and so sea level may go up
25 much faster than we think, should they or should

1 they not do it? And so we give the little
2 arguments here, "it's much less costly if we do
3 it now, why don't we prepare" versus "this is
4 really an unlikely event, why should we buy the
5 insurance?"

6 So we set this up very simply as a
7 benefit/cost calculation, the costs are well
8 known, it's the engineering cost of hardening the
9 terminal, which basically has to do with pulling
10 the wires and cables up a little bit higher, and
11 so forth. The benefit is a little bit harder to
12 determine because it depends on whether or not we
13 start getting extreme levels of sea level,
14 whether the sea level begins to rise much faster
15 than expected at the high end of the numbers that
16 John quoted, or even higher, and that we don't
17 know. So we have a very simply cost/benefit
18 model which depends on two sets of things, and
19 let me just lay them out here, what's called in
20 the risk world the "hazard" which has to do with
21 how the climate is changing, we looked at the two
22 things that John talked about in his study, which
23 is how much do the seas rise, and so there's both
24 the thermal expansion of the oceans which is
25 relatively well known, that's a process people

1 understand well, and then there's the fracturing
2 of the Greenland and Antarctic ice sheets, which
3 people don't understand nearly as well, and does
4 that accelerate? Does that take off?

5 And then there's this change in storm
6 surge frequency, you know, this 100-year storm
7 that's become a 50-year storm, that's become the
8 30-year storm, how does that change? And so
9 that's the hazard. And then in thinking about
10 what you need to do now, that connects with
11 what's called the "vulnerability," which has to
12 do with how long is this piece of infrastructure
13 going to last? Okay, when is the next upgrade?
14 And then what risk of annual flooding can we
15 tolerate before we need to spend significant
16 money to respond?

17 So if you knew each one of those things,
18 you could stick into a relatively simple
19 cost/benefit model and calculate the net present
20 value and decide whether it passed the
21 cost/benefit test to buy this hardening or not.
22 And this is all laid out, that's the reference
23 for the paper where this is.

24 But the fact is, we don't know any of
25 those things for sure and so what we do is we

1 look at a wide range of terminal lifetimes, a
2 wide range of essentially disruption costs that
3 people could deal with, we look at a wide range
4 of different sea levels, essentially the range
5 John looked at plus a meter, and a wide range of
6 storm surge or change in the frequency of the
7 storms.

8 So this little graphic suggests what we
9 chose to do, we essentially take 500 different
10 plausible futures, 500 different combinations of
11 vulnerability and hazard, so some with very
12 extreme sea level and very invulnerable terminal,
13 and vice versa, in all different combinations,
14 you run it through the model, you get these many
15 hundred futures, and the first point to make is
16 that this helps reduce gridlock because if you
17 have people, you're showing the analysis to
18 people who have different expectations, and not
19 surprisingly often people's expectations
20 correlate really well with their policy
21 preferences. You've got their expectations in
22 the model, so it gives much better buy-in to this
23 analysis.

24 This then lays out in a chart the answer
25 for each of the cases we ran, so for most of the

1 cases the benefit/cost of this infrastructure
2 investment is negative, so it's over on the left,
3 and if you're over there the best thing to do is
4 just be reactive, not make this proactive
5 investment; if you're on the other end, there's
6 this long tale of cases where this investment
7 pays off -- sometimes big time -- and if you're
8 there you should make the investment.

9 So now that's somewhat helpful, but the
10 key question is, what distinguishes the ones to
11 the right of the line from the ones on the left
12 of the line? So it turns out this is just a big
13 database of cases, you can do some statistics on
14 it, and it turns out if the terminal lifetime is
15 at the very far end, about 75 years or longer, if
16 the abrupt sea level rise is fast, and this is a
17 combination of when it accelerates and how fast
18 it accelerates, but essentially if it happened
19 soon it would be about 14 millimeters a year.
20 And then how much does the change in the
21 frequency of the storm, and if that changes just
22 a little bit, and it turns out that it really
23 doesn't matter how sensitive they are to future
24 flooding, that turns out not to be important at
25 all for this analysis. So if those three things

1 happen, then you ought to harden at the next
2 upgrade; if not, not.

3 So one important thing to note is that,
4 in this world of uncertainty, this is actually a
5 really concrete thing, you know that for sure,
6 okay, even if you don't know the probabilities or
7 anything, so this is a concrete bit of
8 information. Now, should they harden at the next
9 upgrade? Okay. So now we have to think how
10 likely might that vulnerable scenario be, that
11 set of conditions where you would harden, and
12 here is where we can now start mining the climate
13 science and other information to see what we
14 learn. So given the shape of those cases, it
15 turns out you need the conditions that I showed
16 you on the previous slide to be more than about
17 seven percent likely, so a little bit less likely
18 than about one in 10 if they are, so if they are
19 a little bit less likely than one in 10, you
20 should buy this upgrade.

21 So I won't go into the details of this,
22 but we took a variety of different bounding
23 cases, including some of the information that
24 John talked about, some of the California State
25 Guidance, a couple of other studies, and you fit

1 some statistics to that, and it turns out that
2 these extreme rates of sea level rise are no more
3 than -- it says 16 there, but no more than about
4 15 percent likely, so it's hard to make a case
5 that they would be any more likely than that.

6 And there really isn't much experience
7 with the terminals lasting anywhere near 75
8 years, they've been more like 20 years, and at
9 the time we did this, and I think it's changed a
10 little bit, but not that much, there was really
11 no evidence to suggest that you would get storm
12 increase frequencies. So for this particular
13 investment, it turned out that it was probably
14 appropriate not to buy this insurance. We looked
15 at a variety of different facilities in the Port
16 of LA and there was one, a bridge, which would
17 both likely last longer than the terminals and
18 was lower down, so that was one that it might
19 make sense for them to go to their engineering
20 feasibility studies and do that. And then
21 there's a variety of parts of the Port, the rail
22 lines and things like that, that they would
23 probably need to worry about. But for this
24 particular set of infrastructure, this was the
25 answer.

1 So this was a very sort of one-
2 dimensional case where we looked at just one of
3 the pieces, so John showed a whole bunch of
4 different pieces of infrastructure, this was just
5 one, but gave a sense for what the implications
6 for sea level rise for things you're doing now.
7 We've done the same sort of approach in a whole
8 variety of different contexts with much richer
9 sets of options, and so I list a couple of them
10 here, and particularly the Bureau of Reclamation
11 Colorado River Basin Supply and Demand Study
12 where California participated with the other six
13 parties of the Colorado Compact, and that looked
14 at hundreds of different supply options and went
15 through a process like this and came up with a
16 sorting of what you needed to do now and then
17 what could be deferred until later with climate
18 change. This sort of process underlies the
19 recent Louisiana Master Plan for a Sustainable
20 Coast, a bunch of World Bank -- I should have put
21 the -- we do work like this for the Department of
22 Water Resources for the State Water Plan, and
23 then some work in Jamaica Bay. And this is just
24 a picture of -- the main point here is that this
25 sort of process is very powerful in helping

1 people who have reasons to disagree with one
2 another, to come to consensus on where their
3 vulnerabilities lie, where their strengths lie,
4 and coming up with plans that are well matched
5 and robust across a wide -- and having people
6 come to consensus on it -- that are robust across
7 a wide range of futures. Often by starting with
8 a plan, having clear signposts that they're
9 watching which are tied to these vulnerabilities,
10 and having clear contingencies that people can
11 agree to take if those signposts are reached.

12 Just a quick summary, that you often need
13 integrated and adaptive plans to deal with these
14 sorts of risks and this idea of running the plan
15 backwards, stress testing proposed plans over
16 many futures can have a variety of beneficial
17 effects. So thank you.

18 MS. CHAN: Thank you. So I'm going to
19 start with a couple of just mechanical or
20 clarifying questions for Professor Radke and then
21 I have some more provocative questions, and then
22 I'd like to open it up for the panelists to ask
23 each other questions. I find that sort of
24 illuminating every once in a while.

25 So Professor Radke, I know you had made

1 reference to a couple things in passing and I
2 just wanted you, for the benefit of our audience,
3 to explain them a little more; you made passing
4 reference to a bathtub model versus a more
5 dynamic model, and I was just hoping you could
6 say a few words to explain that. And also, you
7 made passing reference to the fact that wetlands
8 could be an excellent way of addressing flood
9 risk, and I was hoping that you could speak just
10 very quickly to give us a little more detail on
11 that.

12 PROFESSOR RADKE: Okay, is my microphone
13 on?

14 MS. CHAN: Yes.

15 PROFESSOR RADKE: Okay. Yeah, as opposed
16 to a bathtub, or a more dynamic model. So
17 bathtub models, and a lot of people use them,
18 they're quite easy, you just raise the elevation
19 of the seal level, and of course you raise that
20 level to whatever is being predicted. And so if
21 it's 1.4 meters, you just raise it 1.4 meters and
22 see where water inundates. The problem with
23 doing that is that it doesn't account for the
24 movement of water. And so we went to a pathway
25 model and we looked at not just a digital

1 elevation model, which most people use, we
2 integrated something called a digital surface
3 model, and those are the objects on the surface,
4 and we use those to watch the water track its way
5 across the landscape. And at times they're
6 really good barriers either built by humans, or
7 sometimes natural barriers that actually prevent
8 the water from inundating and therefore prevent
9 damage and prevent infrastructure from being
10 impacted. So in our transportation study, we
11 went with this pathway model.

12 Then, you know, we had some great
13 feedback that said, well, why not go with a
14 dynamic model? And we started playing with
15 dynamic models, but the problem is, you know, I'm
16 trying to model areas larger than the entire
17 country of the Netherlands because California is
18 a really big place, and I'm not only trying to do
19 that, but trying to do it right down to the curb
20 level. To try to get a better sense, so I hope
21 one can even think of how much processing this
22 takes in the model, it's a lot of computing, but
23 just to try to make good exact solutions and
24 correct solutions, and trying to get it right.
25 So the inundation models, they not only look at

1 the tides, they also look at the wave action, and
2 that's why we needed to go out and not just
3 predict some elevation, 2.60 which was the 100-
4 year storm event, but we also needed to be able
5 to look at gauging stations that are all over the
6 Bay and Delta areas so that we could better
7 calibrate our model as we were looking at this
8 impact. And so that's why we've come up with
9 this newer model. Now, there are lots of models
10 that you can use to model very tiny areas if
11 you're trying to put in a dock, or you're trying
12 to just do a little bit of change in the
13 landscape, but to model the entire Bay, the
14 entire Delta, has been quite a challenge -- an
15 interesting challenge, and we feel we're getting
16 some good success from doing that.

17 The second question had to do with
18 wetlands -- and let me go back to the first
19 question first -- so we also found that there are
20 objects on the landscape, the digital surface
21 model, that do impact the inundation of water,
22 and if you use the bathtub model, there's not
23 really an impact, and actually if you just use a
24 pathway model there's not a huge impact, as well,
25 objects like buildings do impact the movement of

1 water and the flow of water. And so we actually
2 have had to rebuild our surface model to include
3 every building and every object and this vast
4 area called the Delta in the Bay, and it's been
5 quite exhausting. But, you know, the fact is
6 we're getting much better results and much more
7 real results so that we have a better sense of
8 what will happen. And I really appreciate what
9 Robert Lempert was suggesting and saying, you
10 know, that the closer you can get a sense of
11 what's going to happen, and if you can do this
12 well in advance, then this kind of planning and
13 decision making can be enlightened and we can
14 actually do a much better job at minimal cost.
15 And I just want to go on record by saying if you
16 gave me 90 years to plan something, I could plan
17 it at minimal cost, at minimal expert cost,
18 because I'd have 90 years, and I'd understand
19 that some things might have a life of 75 years,
20 other things might have a life of 50 years, so it
21 really helps us rethink, redesign our
22 transportation infrastructure in an intelligent
23 way because we know what the future is going to
24 bring eventually.

25 The second question was wetlands and this

1 is where the Dutch have learned an awful lot and
2 we can learn from them, that in about 1100, they
3 used to pump water, they used to build levees
4 because they were under sea level, and they would
5 pump the water out and they would dry the area
6 out, and then they noticed that they were getting
7 subsidence and the subsidence exacerbated the
8 problem of being below sea level, so they were
9 actually sinking. And then it took them 100
10 years, so by about 1200, they realized that what
11 they needed to do was keep all of these canals
12 and channels, many of them, and keep them full of
13 water to keep the land moist and to keep the land
14 at somewhat of a constant elevation. And we have
15 a similar thing going on in our Delta in that we
16 have incredible subsidence and some of those
17 islands, there's places on Sherman Island that
18 are 24 feet below the river level, but they
19 didn't start off that way, they started out at
20 river level.

21 And the idea of wetlands, and I suggested
22 that the U.S. Corps had just broken a levee at
23 Hamilton Field and they're trying to create a
24 wetland, and wetlands act as good nature barriers
25 because, as water rises, hopefully the wetlands

1 will grow and the Dutch are trying to do this
2 with some of their levees, as well, they have
3 what they call "horizontal levees," and they try
4 to get these areas to grow, they're very gradual
5 levees, they grow and through time they become
6 less risky. If we build a concrete levee and
7 it's a certain elevation, it's not going to grow,
8 it stays that elevation. And through time, of
9 course, as sea level rises and inundation
10 increases, they're just going to get overtopped.
11 And we can see that in Fukushima, you know, the
12 levee never anticipated the tsunami and it was
13 overtopped quite easily and that levee took very
14 little energy out of the wave, and the wave was
15 incredibly destructive behind the levee. And had
16 we been thinking more green here, and put more
17 vegetation in place, or in that case left
18 vegetation in place, it would have served to take
19 energy out of that wave.

20 Up in Sherman Island there, the western
21 part of Sherman Island flooded years ago and they
22 chose not to rebuild the levee, so it's turned
23 into a wetland, and it acts as a good barrier to
24 any storms because the wave action comes in and
25 it hits this wetland and takes the energy out of

1 the waves, and therefore there's less inundation
2 and less stress on the actual levee on the
3 western side of Sherman Island. And we're
4 finding more and more that growing things is a
5 good way to calm these forces.

6 MS. CHAN: And I know we're just pretty
7 narrowly focused today on sea level rise impacts
8 on transportation, and we're not talking about
9 heat or other climate risks, and we've heard a
10 little bit about wetlands and a little bit about
11 hardening, we haven't had a chance to touch that
12 much on a couple other management options that
13 Professor Radke discussed about changing
14 location, and also design, which are also
15 fruitful topics, which maybe if we have time we
16 can touch on a little bit. But I did want to
17 circle back to Dr. Lempert and ask a question.

18 COMMISSIONER SCOTT: Ann? I was just
19 going to check; before you go to Dr. Lempert, I
20 had a clarifying question also for Professor
21 Radke and I was just going to check and see if my
22 fellow Commissioners did.

23 Professor Radke, thank you very much for
24 your really interesting and informative
25 presentation. The question that I have for you

1 is, you mentioned two or three times actually I
2 think that the Global Circulations Model show
3 that the 1.4 meters is going to be where we're
4 anticipated to be at the end of the century. And
5 so I was wondering why you stopped your modeling
6 at 1.4 instead of potentially looking at some
7 scenarios that might be higher than 1.4.

8 PROFESSOR RADKE: Yeah. Good question
9 because -- so I didn't also talk about the
10 specific Pacific Decadal Oscillation which is,
11 you know, it's like this huge -- the Pacific is
12 this huge bathtub and it sort of oscillates back
13 and forth about every 15 to 20 years, and so
14 right now in San Francisco we're experiencing
15 really low sea levels, but in fact they're at
16 average because it's very very high out in the
17 Western Pacific. And in the next 10-15 years,
18 it's going to oscillate back, so we're going to
19 feel like sea level is really rising rapidly
20 because it will just be sloshing back toward us.
21 And I know that there are lots of people -- I
22 took the average because, I don't know, maybe the
23 fear of people screaming at me, I don't know, but
24 if you take the extreme, the extreme actually
25 might actually be correct, and now that we've

1 seen what's happening in Antarctica, it makes me
2 nervous, I'm very nervous about that, but I took
3 1.4 because that seemed to be the average model
4 and that's what people were saying would likely
5 be. But I also said it would likely happen by
6 2100 and the fact remains, if we stop burning
7 fuel and we stop putting carbon in the
8 atmosphere, I think we're still going to get this
9 effect of 1.4 in 2100. But we did it as 0.5,
10 1.0, and 1.4, and we could have kept going
11 because that level might come earlier or it might
12 come later, but we feel pretty confident that
13 it's going to happen. And again, if I had 90
14 years to plan, and I really appreciate what
15 Robert Lempert had to say because it is important
16 to look at, well, what am I trying to protect?
17 And am I trying to protect something that is
18 built? And if it's built and it has a life
19 expectancy of 75 years, then maybe I shouldn't be
20 too concerned about it. But we could have kept
21 going on and modeling higher and higher to 2.0
22 and 2.5, etc. And I just doing know that it's
23 worth frightening people. And it's a long way
24 off and I was hoping, I guess, that 1.4 was what
25 people are agreeing on, and I also felt that 1.4,

1 whether it's plus or minus, whether it's plus or
2 minus 10 years, would at least get us to
3 understand that we could actually make changes
4 now at very little cost because rather than
5 repairing 880, spending hundreds of millions of
6 dollars repairing 880, next time rethink 880 --
7 and that's one of the highways that's inundated
8 around San Jose -- rethink where we're going to
9 put it and spend our efforts redesigning the Bay
10 Area so that in 90 years we don't have to worry
11 about infrastructure getting inundated,
12 constantly getting inundated and constantly
13 costing money. So that's why we did what we did.

14 COMMISSIONER SCOTT: Great, that's very
15 helpful, thank you.

16 MS. CHAN: And I guess I'll jump in by
17 saying the Safeguarding California Plan
18 references the National Research Council Report
19 that the state invested in with Oregon and
20 Washington, and the projected numbers in there
21 are actually slightly different, the range that's
22 provided for 2100 is actually anywhere from 17
23 inches to 66 inches, so it actually goes past the
24 1.4 meter point.

25 As Professor Radke points out, the

1 further out you go, the more risk and uncertainty
2 there is associated with those numbers. But
3 we're also trying to design our policies here in
4 California for sea level rise to take into
5 account the fact that we don't think it's going
6 to stop.

7 CHAIRMAN WEISENMILLER: Okay. I also had
8 a question. If you turn to page 7 of your
9 slides, you showed Richmond, and I guess what I
10 was looking at was just mentally where the
11 refinery is now.

12 PROFESSOR RADKE: Yeah, let me find my
13 slides here. I'll find them. Richmond, right?

14 CHAIRMAN WEISENMILLER: Yeah.

15 PROFESSOR RADKE: Yes.

16 CHAIRMAN WEISENMILLER: Keep going.

17 PROFESSOR RADKE: Okay. So I've got
18 Richmond.

19 CHAIRMAN WEISENMILLER: Yeah, so you've
20 got Richmond before and after, and it's roughly
21 -- I've got two slides per page, so page 7 --

22 PROFESSOR RADKE: Yes, I see it.

23 CHAIRMAN WEISENMILLER: So it's probably
24 about 13 or 14.

25 PROFESSOR RADKE: Right, page 15-16, I'm

1 looking at it. Did you want to put those up on
2 the screen?

3 CHAIRMAN WEISENMILLER: Yes.

4 PROFESSOR RADKE: So can I share my
5 desktop?

6 CHAIRMAN WEISENMILLER: Sure.

7 PROFESSOR RADKE: Okay.

8 CHAIRMAN WEISENMILLER: Okay, so
9 basically the question is where is the refinery?
10 Particularly as you go through the high storm
11 stuff, it appears the refinery is under, well, at
12 least being flooded.

13 PROFESSOR RADKE: Part of it is being
14 flooded, right. But remember, I think the
15 refinery actually is to the eastern side of these
16 hills.

17 CHAIRMAN WEISENMILLER: Okay.

18 PROFESSOR RADKE: So this area is pretty
19 low lying.

20 CHAIRMAN WEISENMILLER: Right.

21 PROFESSOR RADKE: Yeah. And here's the
22 bridge part here. Okay, so what's your question?

23 CHAIRMAN WEISENMILLER: Yeah, so
24 basically trying to figure out in terms of
25 critical infrastructure, you know, we looked a

1 lot at sort of highways and all, but sort of
2 either refinery location, or oil pipelines, how
3 much have you looked at those?

4 PROFESSOR RADKE: Well, so we are looking
5 at gas pipeline infrastructure right now and
6 working with PG&E under a nondisclosure to try to
7 understand their infrastructure, and the graphics
8 that I showed were from the National Pipeline
9 MTMS Mapping System, but we also have the liquid
10 pipelines and we actually have discussed --
11 because we're trying to understand what the cost
12 of replacing and what the strategies are, not
13 just the strategies, but what the costs are of
14 replacing pipeline infrastructure. And we've
15 also tried to encourage those that we're talking
16 with to also help us with the infrastructure such
17 as at the refinery plants and pump stations and
18 on the ground infrastructure, as well. And they
19 so far have been cooperating and we've been
20 getting where their critical infrastructure on
21 the ground is. And at the end of this study,
22 hopefully we'll know which areas are at great
23 risk and which areas are not.

24 CHAIRMAN WEISENMILLER: Yeah, because the
25 example we're looking at with transportation, one

1 of the questions is which of our transportation
2 infrastructure is going to be impacted.
3 Obviously, oil is a key part of the
4 transportation system or a larger part than
5 natural gas at this stage.

6 PROFESSOR RADKE: Well, our whole point
7 about interconnectedness is that, you know, both
8 of them impact each other. Certainly if oil
9 can't come into the Bay Area and be refined,
10 we've got an issue and we've got a problem. We
11 actually haven't inundated with our new model the
12 area around Richmond, and up in Martinez, but we
13 will. And of course, with our modeling looking
14 at transportation we think Martinez looks pretty
15 risky. But oil is also transported by rail, as
16 well, so certainly it is expensive to bring it
17 into the Port of Richmond, and all we can do is
18 point out what pipelines will be impacted. It is
19 certainly up to the pipeline managers and owners
20 to decide how they're going to deal with what
21 we've predicted as being an impact to their
22 infrastructure. So I don't know if that means -
23 I don't know what that means. We're still
24 modeling and we're still trying to get back to
25 them with what parts of their infrastructure will

1 be impacted, when, and some of it will be
2 permanently possibly underwater and others will
3 just get impacted by the inundation from an
4 extreme event. And so we're right in the middle
5 of that research right now. I wish I could tell
6 you the answers. I don't have the answers yet.

7 CHAIRMAN WEISENMILLER: No, and some of
8 these locations obviously have been refinery
9 sites for well over 100 years, so in terms of
10 potential toxics on the site, it can be
11 relatively high.

12 PROFESSOR RADKE: Well, that's true.
13 That's true. You know, the concern in New
14 Orleans was that there was 139 miles, I think, of
15 pipeline that had been inundated after Katrina
16 for several months before they were able to pump
17 the water out. And I guess they checked some of
18 the wells and they'd been compromised. So they
19 quickly changed out the pipe. And we don't know
20 how they're going to respond, we're still
21 processing so much every day so we can get them
22 predictions of what's going to be inundated so
23 that they can take a look and make decisions
24 about how they might handle that. The very last
25 slide, if you go to the very last slide, we show

1 this fragmentation of inundation, and all those
2 little red chunks -- and this is just a
3 preliminary model, not at the highest resolution,
4 and you're seeing bits and pieces of all those
5 pipelines being overtopped, or at least at some
6 point they're being impacted. And we don't know
7 what decisions they would make how to change
8 that. They do have -- pipelines do go underneath
9 the Sacramento River and they do go underneath
10 the Bay, but they're special pipelines rated and
11 designed to be permanently underwater. But
12 anything that is up on the land, although it's
13 wrapped so that it shouldn't have saltwater
14 intrusion and it shouldn't be compromised, they
15 were concerned about the weight, the weight of
16 water and the slushing around, the water on top
17 of this pipeline, and they showed great concern
18 and that's something that we weren't concerned
19 about going into the meetings with the pipeline
20 operators, but coming out we realized it was
21 something we hadn't anticipated.

22 CHAIRMAN WEISENMILLER: Thank you.

23 PROFESSOR RADKE: Does that answer your
24 questions?

25 CHAIRMAN WEISENMILLER: Yes.

1 PROFESSOR RADKE: Thanks.

2 MS. CHAN: All right, this is Ann again

3 and I had a question mostly directed to Robert,

4 but open to both panelists. I know we had the

5 Port of LA study that you showed and you talked

6 about it in terms of whether or not you want to

7 buy that insurance if you run the model and it

8 comes out a certain way; so I'm going to ask a

9 question about multiplicity of actors in the

10 system. So obviously we have lots of earthquakes

11 in California and we can think about it in sort

12 of a similar way, earthquakes, somewhat low

13 probability, but very high catastrophic costs

14 when they actually do have them for any

15 individual actor or anyone managing a certain

16 asset may not make sense, but societally if we

17 get hit with one of those, we still need to

18 figure out what to do, disaster appropriations,

19 that kind of thing. In terms of climate change

20 risks, we're seeing things like the National

21 Flood Insurance Program really decimated by these

22 increasingly frequent megastorms, as they're

23 called. So I wanted to see if your models or

24 your studies have looked at multiplicity of

25 actors, particularly for those of us that work in

1 the policy arena and set state policy, also
2 working with our federal partners on federal
3 policy looking at it from more of a public policy
4 standpoint, if you could speak about that.

5 Thanks.

6 DR. LEMPert: Yeah. The quick answer is
7 yes, and we have. I think there's actually two
8 pieces to your question; I mean, one is the
9 timelines and the other is essentially sort of
10 multiple assets at risk, and so one of the
11 drivers in the Port of LA study that I showed you
12 is the interplay between the lifetime of the
13 capital stock and the sea level rise, which is I
14 think very different than earthquakes, which
15 could happen at any time.

16 MS. CHAN: Right.

17 DR. LEMPert: But on the multiplicity of
18 actors, yeah, that was a central feature of all
19 the pieces I showed you on my final slide. So
20 since we were discussing, you know, the Louisiana
21 Coast, we talked about that, which was that study
22 basically took flood maps like we've been looking
23 at and then played many hundreds of combinations
24 of different, you know, wetlands restoration
25 versus levees, and so forth, and basically played

1 out many hundreds of combinations of these things
2 within essentially the \$50 billion amount of
3 money that the State of Louisiana had to spend,
4 in interaction sessions with stakeholders,
5 basically the state they're head of, and office
6 which was responsible for the coastal plan, and
7 so they had about 30 or 40 representatives with
8 basically monthly meetings for about two years,
9 which were essentially interactive what ifing,
10 you know, what happens if we take the money from
11 this levee and put it here, well, that protects
12 this parish, but the levee here will increase the
13 flood risks on the neighboring parish, so maybe
14 we ought to add a little bit of wetland -- so
15 basically interactive designs of these things to
16 come up with something, which ended up passing
17 the Legislature unanimously because it had this
18 ability to balance these competing interests, not
19 only flood protection, but recreation, keeping
20 their ports safe, the fisheries, so there's a
21 whole bunch of competing interests, competing
22 people, and then playing that out against a range
23 of different sea level rise and storm surge
24 scenarios so that you're basically giving
25 everybody a reasonable tradeoff with a wide range

1 of different potential stressors.

2 So, yeah, dealing with multiple interests
3 is definitely at the heart of this. And clearly
4 in the Colorado Basin Study, which there's
5 clearly up river and down river, high water rise
6 and low water rise, and so that has to balance
7 among those, as well.

8 MS. CHAN: Sure. So having seen John's
9 presentation, is there anything that you would
10 want to ask him, or that you found provocative?

11 DR. LEMPERT: Well, let me start with a
12 really techy question, which is: John, how long
13 does it take to run a case on your models? And
14 how hard or easy is it to shift things around?
15 You move pipelines, you know, add a little bit of
16 wetlands, and so how easy would it be to play
17 this game of seeing how your policies might
18 evolve over a couple of decades to protect
19 against some of the risks you showed?

20 PROFESSOR RADKE: Yeah. Is my mic open?
21 Okay, so I started off thinking that I could get
22 by with eight terabytes of disk, and I was just
23 fooling myself. And now we're looking at just
24 every researcher carrying a terabyte in their
25 pocket, I think. So it's a lot of modeling and

1 it takes a long time and we've been trying to
2 design computers here that will go faster, but it
3 tough, it is tough. And this is why, if you've
4 got One Scale, it's easy to model, but you're
5 missing the subtleties, and my whole point was at
6 One Scale you miss critical levees, and some of
7 the natural levees that actually protect the
8 landscape; the one slide that I showed, that if
9 you do it one way you miscalculate and you over-
10 flood the areas. So it takes a long time and the
11 transportation study that I did on the Delta that
12 was just looking at first responders, so
13 basically what I did was I had every first
14 responder respond to every household in the Delta
15 after an event took place, and it would run about
16 two weeks, maybe less than two weeks, on each
17 flooding of each island, and of course, we
18 assembled it altogether. So it takes a long time
19 and you have a dedicated server to do that. So
20 the processing takes a long time.

21 Now, the idea of the scenario of changing
22 some infrastructure, it turns out that that's not
23 that difficult because we sort of, oh, we learned
24 the hard way, we were all set, we had our models
25 ready to go, and we were feeling very proud, and

1 we brought in an expert hydrologist from the
2 Netherlands, and we took him out into the Delta
3 and he just looked around and pointed out all the
4 things that we had done wrong to run their model.
5 And part of it was we had dealt with education in
6 sort of an incorrect way, and so we were able to
7 then quickly change our strategy and started to
8 remove vegetation, and start to remove things
9 from our surface model, which means we became
10 sort of expert at running out different
11 scenarios. But it turns out that that is
12 something that is real, so if a design group
13 said, "Wait a minute, what if we make these
14 changes and the following could be built, and the
15 following could occur, what would be the result
16 of that?" And it turns out we could do that,
17 it's not difficult anymore simply because we've
18 gone through that entire process of just trying
19 to get it right, the modeling in the first place.
20 I don't know if that answers your question.
21 We're still trying to tune -- GIS is easy when
22 you don't have massive databases, and when you
23 get massive databases it gets harder and harder
24 and you have to start to rethink how you solve a
25 problem and redesign the solution, the algorithm

1 solution. So, yeah, I'm exhausted.

2 DR. LEMPERT: Okay (laughing).

3 PROFESSOR RADKE: I'm thinking back to a
4 time where I said, "I don't think I want to do
5 this," but anyway, I'm glad that we did it.

6 MS. CHAN: I know we have a lot of folks
7 with us in the audience, I want to kick it back
8 to the Commissioners to see if they have any last
9 questions before we open it up.

10 CHAIRMAN WEISENMILLER: Yeah, I have one.
11 So on your list of the conditions where basically
12 they pass the cost/benefit test, I was surprised
13 the discount rate didn't get in that.

14 DR. LEMPERT: Oh, yeah, we didn't vary
15 that and, had we, it would have. In this
16 particular problem, it would get tied up with
17 disruptions and how much you thought it would
18 disrupt operations and such in the future, so we
19 basically assumed in this particular study that
20 in the future you would have enough warning to do
21 an orderly hardening of the terminal in the
22 future, so it was essentially -- it was only cost
23 of capital and not sort of the social costs of
24 running a problem. So we basically -- the short
25 answer is we set up the problem to make that much

1 less of an issue than it is in other cases.

2 CHAIRMAN WEISENMILLER: Okay, thanks.

3 COMMISSIONER SCOTT: I did have a
4 question of you also. You mentioned that the one
5 process where you showed all the folks sitting
6 around the table together, and that took about
7 two years, and how long did the port process
8 take? And, then, if you were to do this with
9 other sort of critical pieces of infrastructure
10 around the state or other areas, is there a
11 typical timeframe for how long it takes?

12 DR. LEMPert: Yeah, the answer is no, it
13 depends; the two years was much more of a social
14 process, so with the port it was much quicker, we
15 did four small workshops with them and the
16 calculations were much quicker. For individual
17 pieces of infrastructure, you know, I mean I
18 think it's a pretty quick process, it depends on
19 if you've got a model which looks at the
20 performance and you've basically got a pre-
21 feasibility study, or something like that, that's
22 sort of a few weeks, and then the rest of the
23 time would be the social process, depending on
24 how much of the community you wanted to bring in.

25 COMMISSIONER SCOTT: That's great. Thank

1 you. Well, so I would like to say just a hearty
2 thanks to Deputy Secretary Ann Chan for being
3 such a thoughtful moderator and to both Professor
4 Radke and to Dr. Lempert for just really
5 interesting, I think, fascinating and well
6 researched information and your presentation of
7 them here today. So thank you very much for
8 that.

9 MS. CHAN: Thank you.

10 COMMISSIONER SCOTT: I'm going to open it
11 up to see whether or not we have public comment
12 and turn to my IEPR team to see if we've got any
13 blue cards.

14 MS. RAITT: I didn't receive any blue
15 cards, but is there anyone in the room who wanted
16 to make comments or have questions? No. And
17 then on WebEx, I don't think we have any
18 questions. We do have one person on the phone and
19 we could open up that phone line and see if that
20 person has a comment. Okay, it's open. If
21 you're on the phone, this is your opportunity to
22 make a comment or ask a question.

23 MS. SCHMIDT-POOLMAN: Yes, hi. This is
24 Martine Schmidt-Poolman. I actually had a
25 question for Dr. Lempert about the stakeholders

1 and whether he has an idea based on working with
2 them on how aware they were of this, I guess what
3 you also noticed, this inter-connectivity of the
4 various infrastructure around the ports. Did you
5 notice that they became more aware, or weren't
6 aware?

7 MS. RAITT: Oh, and I'm sorry, so could
8 you also give us your name and affiliation,
9 please?

10 MS. SCHMIDT-POOLMAN: Oh, this is Martine
11 Schmidt-Poolman and I work at U.C. Berkeley.

12 MS. RAITT: Thank you.

13 MS. SCHMIDT-POOLMAN: And I work with
14 John.

15 DR. LEMPERT: Okay, great. Hi. Yeah,
16 that's a great question. The Port of LA stay was
17 actually very limited and we just worked with
18 people within the port design team, but on some
19 of the other work I mentioned, some in Louisiana
20 and the Colorado Basin, yeah, no, part of the
21 exercise is helping people become more aware of
22 the interconnectedness. I mean, putting a levee
23 in one place may reduce flood risks behind the
24 levee, but may increase flood risk for the next
25 people down the coast. And again, part of the

1 two-year social process is people becoming much
2 much more aware of that and in some sense
3 starting to get an intuitive sense with how that
4 works, so that they can better adjudicate and
5 negotiate with one another about the tradeoffs
6 and how they work, and the model essentially
7 informs their ability. So, yeah, you do see
8 people becoming much more cognizant of that as
9 you go through the process.

10 MS. SCHMIDT-POOLMAN: Okay, great. Thank
11 you.

12 MS. RAITT: It turns out we have two
13 questions also coming from WebEx by write-in, so
14 I'll read those out loud. The first one is: What
15 bridge at POLA needs to be replaced according to
16 the RAND study? And the second question is: What
17 is the Vincent Thomas Bridge? And those
18 questions are from Jerilyn Lopez-Mendoza at SoCal
19 Gas.

20 DR. LEMPERT: The bridge that we looked
21 at, we didn't say it needed to be replaced, we
22 said that when it came time to do its upgrade
23 that the Port might look at more detail, you
24 know, that it passed essentially the screening
25 test that they ought to take it seriously, so

1 it's the Alameda and Harry Bridges Crossing is
2 the name of that particular piece, that bridge
3 was the one that they ought to pay attention to.

4 MS. RAITT: And the other question was:
5 What is the Vincent Thomas Bridge?

6 DR. LEMPert: That's the big one across
7 the Port of LA and the Port of Long Beach.

8 MS. RAITT: Thank you.

9 COMMISSIONER SCOTT: Can you mention that
10 into the microphone?

11 DR. LEMPert: Unless I'm remembering
12 wrong, that's the one that connects the Port of
13 LA and the Port of Long Beach, right?

14 MS. RAITT: Okay, I don't think we have
15 any more questions.

16 COMMISSIONER SCOTT: Okay, well I would
17 again like to reiterate my thanks to our IEPR
18 staff and to the Energy Commission staff that
19 helped put together this really interesting
20 workshop. Thank you again to our terrific
21 speakers, I thought that was just really
22 informative and I learned a lot, it was very
23 interesting, and to Deputy Secretary Chan for
24 being a terrific moderator. And from my
25 perspective here, I would reiterate what the

1 Chair mentioned at the beginning of the workshop,
2 which is that our transportation sector is
3 responsible for about 40 percent of the
4 greenhouse gas emissions here in the State of
5 California, and so ratcheting those down is going
6 to be of utmost importance. I think for the last
7 few workshops that we've had so far on the IEPR,
8 a lot of the speakers have discussed the urgency
9 for getting these reductions in place and, in
10 addition, getting clean air pollutant reductions
11 in place from the transportation sector. And I
12 think that the presentations we got here today
13 just put a really fine point on the climate
14 imperative for why we need to do that, and so I
15 would thank you again and see whether or not
16 either of my fellow Commissioners has any closing
17 remarks for today.

18 CHAIRMAN WEISENMILLER: Again, we were
19 certainly sorry to have missed the third
20 panelist, but certainly encourage sort of that
21 written submittal and again going forward, if
22 people have questions or comments, I don't know
23 if there's a period when comments are due,
24 Heather?

25 MS. RAITT: Yes. Comments are due June

1 7th.

2 COMMISSIONER DOUGLAS: Great. Well, I'll
3 just join Commissioner Scott and Chair
4 Weisenmiller in thanking the panelists and Ann
5 Chan for moderating, and the IEPR staff for
6 helping pull this together. It was very
7 informative and we'll look forward to more
8 workshops on reducing emissions and otherwise
9 providing benefits from the transportation
10 sector.

11 COMMISSIONER SCOTT: We're adjourned.
12 (Whereupon, at 4:37 p.m., the workshop was
13 adjourned.)
